ABSTRACT

This research determines the incidence of community-acquired pneumonia cases in the Guna Yala region during the year 2023. The specific objectives include calculating the incidence rate of pneumonia in the Guna Yala region, identifying the risk factors associated with pneumonia in children and adults, comparing the incidence of pneumonia among different age and gender groups, and proposingrecommendations for the prevention and control of pneumonia in the region.

Keywords: Acquired Pneumonia; Guna Yala; Incidence; Mechanical Ventilation; Patient Transfers.

RESUMEN

Esta investigación se determina la incidencia de casos de neumonía adquirida en la comunidad de la Comarca Guna Yala durante el año 2023, dentro de los objetivos específico:calcular la tasa de incidencia de neumonía en la comarca Guna Yala, identificar los factores de riesgo asociados a la neumonía en niños y adultos, comparar la incidencia de neumonía entre diferentes grupos de edad y sexo y proponer recomendaciones para la prevención y control de la neumonía en la región.

Palabras clave: Neumonía Adquirida; GunaYala; Incidencia; Ventilación Mecánica; Traslados de Pacientes.

INTRODUCTION

Community-acquired pneumonia (CAP) is an infection of the lung parenchyma acquired outside of a hospital setting.(1) Different guidelines define it differently, although it is generally accepted that symptoms must last less than 14 days and must have started in patients who have not been in contact with a healthcare setting for 14 days or within the first 48 hours of admission.

According to WHO data, pneumonia is the leading cause of infectious death in children worldwide. In 2019, it caused 740 180 deaths in children under five, accounting for 14 % of all deaths in this age group. Most of these deaths occur in low-income countries.(1)

METHOD

The study population is between 1 and 65 years old and attends health centers in the region in different districts such as Narganá, Ailigandí, and Tubuala. These health centers collect patient data to monitor them and provide appropriate treatment. Within this, there are diagnostic criteria to confirm a case of community-acquired pneumonia. We follow the diagnostic criteria according to the ATS (American Thoracic Society), primary criteria: need for mechanical ventilation and presence of septic shock; minor criteria: systolic pressure <90 mmHg, multilobar radiographic involvement, and PaO2/FiO2 < 250 mmHg.

CRITERIOS ATS/IDSA PARA ADMISIÓN UCI	
Criterios Mayores —al menos 1—	**Criterios Menores —al menos 3—**
Necesidad de Ventilación Mecánica	FR>30
	$PaFiO_2$ ≤250
Soporte Vasopresor	Infiltrados Multilobares
	Confusión
	BUN >20
	Leucopenia <4.000
	Trombocitopenia <100.000
	Hipotermia <36ºC
	Hipotensión PAD<60 PAS<90

Figure 2. Distribution of health facilities by level of care and degree of complexity

According to the criteria (figure 1), if the patient meets more than four of the signs and symptoms mentioned, an assessment and physical examination of the patient will be performed, taking into account that not only the criteria are used to diagnose CAP, but also complementary tests such as complete blood count (CBC), due to the limited availability of resources and access to them, only the white blood cell count will be taken into account for the assessment and to conclude the diagnosis.

On the other hand, the severity of patients' signs and symptoms must be considered when deciding whether to transfer them.

According to MINSA (2020), "The health facility network in Kuna Yala is limited to primary care; there are no secondary care facilities. It should be noted that although we have a Regional Hospital, it does not have the installed capacity or human resources to be considered a second-level care facility, so in practice it functions as a first-level care facility like the rest of the facilities in the network (figure 2).

Due to the above, our healthcare network is incomplete, and people who require more specialized care must travel to the capital city to meet their needs for specialized consultations, surgical procedures, and long-term hospitalizations.[2]

MINSA (2018) states, "Each health district in the region has a health facility located at its respective headquarters. Close coordination between each health institution and each district health headquarters facilitates the process of caring for the population. Hospitals and most health centers with beds have a complete basic team consisting of general practitioners, nurses, nursing technicians, statistics technicians, pharmacy technicians, laboratory assistants, ship operators, nutritionists/nutritional assistants, and health educators/promoters. The teams at peripheral health institutions, health posts, and primary health care centers are relatively small given their human resource conditions. We believe it is necessary to strengthen human resources in these areas. Due to their functional diversity, peripheral facilities, in addition to their modernization, cause work overload and burnout syndromes.[4]

DEVELOPMENT

Patient Transfers

According to the Panamanian Ministry of Health (2020), The region has ground transportation equipment for patient transfer (ambulances), whose launch point is in the Llanos de Cartí area (Cartí health area). The nearest referral facility is the Chepo Hospital, which does have specialists in the area. Patients from the health areas of Cartí, Río Sidra, and Narganá are frequently transferred by sea and land to that referral center, while patients from facilities located in the rest of the health areas, such as Playón Chico, Ailigandí, Ustupu, Mulatupu, and Puerto Obaldía, the primary means of transport is by air, with the support of the National Air Service (SENAN). For these patients, the referral facilities are the Santo Tomas Hospital, the Social Security Fund (CSS), the Children's Hospital, and other government or private institutions located in the capital city. It should be noted that if air transport is not possible due to the unavailability of aircraft or weather conditions that make airspace impassable, patients are transported by sea to Llanos de Cartí and then by ambulance to the Chepo Hospital.[2]

Impact

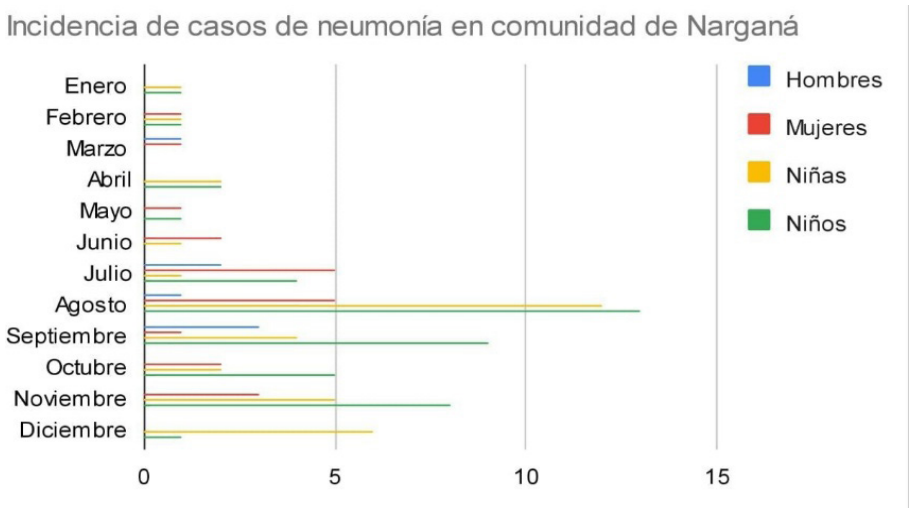

Figure 3. Incidence of pneumonia cases in the community of Narganá

- General incidence. During the year (2023), 145 cases of community-acquired pneumonia were reported in Kuna Yala. This represents an incidence of 5 cases per 1000 inhabitants. (Source: Epidemiology

Service of the Ministry of Health, Kuna Yala Region).

- Spatial Distribution. The highest concentration of cases was observed in the district of Narganá, followed by Ailigandí. This uneven pattern could be related to several factors such as population density, access to health services, and risk factors.
- Temporal Distribution. A clear seasonal trend was observed, with a peak in cases during the winter months (July to October). In the case of Narganá, August recorded the highest number of cases, with 13 reports in boys and 12 in girls. This seasonal variability could be associated with climatic factors, such as low temperatures and higher humidity, which favor the transmission of respiratory pathogens (figure 3).

On the other hand, in Ailigandí, November saw a predominance of cases in women (figure 4).

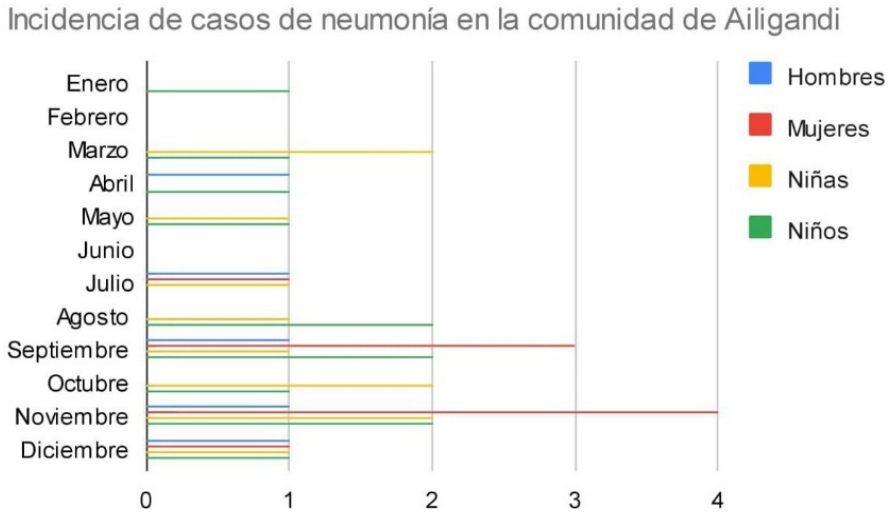

Figure 4. Incidence of pneumonia cases in the community of Ailigandí

Risk factors

Community-acquired pneumonia is a significant public health concern, especially in populations with specific risk factors such as those living in the Guna Yala region. However, there are risk factors that could be particularly relevant, as lack of access to safe drinking water, exposure to wood smoke, chronic diseases, age, and malnutrition, which could specifically lead people in the community to suffer from this disease.

According to the Social Security Fund (2021), One of these factors is age, with an increased risk in people over 65 years of age, chronic lung diseases, and diseases that cause immunosuppression (which lower the body's defenses), as well as children under 5 years of age, who do not yet have sufficiently strong defenses. However, some behaviors or habits put people at risk of contracting the disease, the most important being frequent alcohol consumption and smoking.[3]

Water is supplied in the Guna Yala region through a rural aqueduct system. Some wells are untreated, while in other cases, there is drinking water, as shown in (figure 5).

Aspecto	Cantidad	%	# de Habitantes	%	# de casas	%
Comunidades	59		33,469		5,133	
Acueductos	35	59.3

Figure 5. Water supply mechanism

The Guna Yala community has been dumping sewage directly into the sea for many years. This consists of a hanging toilet on the beach with four wooden or cement supports, lined with palm leaves or other materials. Some have flush toilets, but they discharge directly into the sea, and 3,8 % have septic tanks, as shown in (figure 6).[4]

RECOMMENDATIONS

Improve access to healthcare

- Expand health tours to more neglected or hard-to-reach areas, seeking to improve vaccination coverage to prevent vaccine-preventable diseases.
- Ensure that facilities have the necessary supplies and equipment to treat patients.
- Hire more human resources, including medical specialists who make weekly visits with good salaries

to provide more timely health services.

- Train health center doctors and nurses on the most common diseases according to their incidence.

Implement early prevention strategies

- Education based on educational talks promoting hand washing and personal hygiene to prevent the spread of respiratory diseases.
- Raise awareness in the community about seeking early care from health services to ensure timely treatment and avoid complications.

Improving living conditions and reducing pollution

- Promote improved ventilation in homes and reduce exposure to indoor smoke, especially from wood- or coal-burning stoves.
- Develop strategies in conjunction with the local government to control waste and sewage in communities.
- Promote the use of improved (gas) stoves to reduce exposure to indoor smoke.

CONCLUSIONS

The study on the incidence of community-acquired pneumonia (CAP) in the Guna Yala region in 2023 shows that this public health problem is of great relevance, with a rate of 5 cases per 1000 inhabitants and a total of 145 reports. The districts of Narganá and Ailigandí have the highest concentration of cases, which could be linked to their population density and limited access to health services. Factors such as restricted access to safe drinking water, poor sanitation, and continuous exposure to wood smoke inside homes significantly influence the prevalence of the disease, especially among children under five and people over 65. A seasonal pattern was observed, with increased cases during the coldest and wettest months, coinciding with the general trend for respiratory infections in similar climates. August was a month with a notable increase in cases in Narganá, highlighting the need to adopt preventive measures during critical periods.

The study also points out that the health infrastructure in the region is limited, consisting mainly of primary care centers and no secondary hospitals, which means that seriously ill patients must be transferred to the capital, either by air or sea. This presents a significant obstacle to rapid access to medical care, and factors such as weather conditions and lack of resources exacerbate the situation. It is therefore urgent to improve the local health system, including increasing medical visits to remote areas, ensuring that health centers are well-stocked, and providing sufficient health personnel. It is also crucial to carry out community awareness campaigns that promote preventive measures such as respiratory hygiene and improve living conditions by reducing exposure to smoke in homes and promoting adequate sanitation.

The combination of preventive strategies, improvements in health infrastructure, and community education can significantly reduce the incidence of pneumonia in Guna Yala. However, for these actions to have a real and lasting impact, they must be implemented sustainably and adapted to the specific needs of the population.
